

Homework I

Math Terminology · Speaking Math

Name: _____

Instructions

Complete the homework using **PEN**! If you have any questions or thoughts, write them down using a different color pen next to the problem/concept. Some homework questions are written intentionally vague, you should try to find them. Some information written may also contradict what you've already learned, you should try to find them.

Part 1 — Terminology Practice

[100 pts]

Foundation (45 pts)

1. [20 pts] Fill in the table for each term in $4x^3 - 3x^2y + 7x - 5$.

Term	Coefficient	Variable(s)	Exponent(s)
$4x^3$			
$-3x^2y$			
$7x$			
-5			

2. [15 pts] Underline each term. Write the number of terms in the blank.

(a) $3a^2b - a + 4b^3 - 1$

Number of terms: _____

(b) $x^2 + x + 1$

Number of terms: _____

3. [10 pts] True or False. If false, write the corrected version on the line.

(a) T / F x has a coefficient of 1. _____

(b) T / F The expression -15 has no terms. _____

(c) T / F A constant is not a term. _____

(d) T / F $12x^3$ and $12x^2$ are like terms. _____

Application (35 pts)

4. [10 pts] Read the expression below out loud as one complete English sentence. Write what you would say.

$$(x + 2)(x - 1)^2 + 12$$

5. [15 pts] Write an algebraic expression for each description.

(a) “Five times a number, squared”

(b) “Three terms: negative four times y^3 , twice y , and one”

(c) “A number times itself, minus the same number”

6. [10 pts] A classmate says: “In $x^2 + x + 1$, the x -term has no coefficient — there’s no number written in front of it.” Are they right? Explain.

-

Part 2 — Speaking: How to Say Algebra Out Loud

Read this section carefully. You will write expressions in English at the end.

You can write algebra faster than you can say it. That’s fine — but if you can’t say an expression out loud, you don’t fully own it yet. Reading your work aloud is one of the best ways to catch mistakes, and every math class from here on will expect you to communicate verbally. This section teaches you the conventions that mathematicians actually use.

Rule 1 — Saying Powers

Single-variable powers: $x^2 =$ “ x squared,” $x^3 =$ “ x cubed,” $x^4 =$ “ x to the fourth.” When there is a coefficient, say it first: $3x^2 =$ “three x squared.” Coefficient, then variable, then power — same order as left to right.

Rule 2 — The Word “Quantity”

Whenever you see a **group** — something inside parentheses — you say “**the quantity**” before it.

$$(x + 2) = \text{“the quantity } x \text{ plus two”}$$

“The quantity” tells your listener: what I’m about to say is grouped together. Think of it as speaking the open parenthesis in words.

$$(x + 2)(x + 1) = \text{“the quantity } x \text{ plus two, times the quantity } x \text{ plus one”}$$

Pay attention to where the comma is! This is crucial in both speaking and writing.

Rule 3 — Powers on Groups

When an exponent sits on a whole group, say the group first, then the power at the end.

The exponent attaches to the group immediately in front of it.

$$(x + 1)^2 = \text{“the quantity } x \text{ plus one, squared”}$$

$$(x + 2)(x + 1)^2 = \text{“the quantity } x \text{ plus two, times the quantity } x \text{ plus one, squared”}$$

Note: “squared” attaches to $(x + 1)$ only. If the entire expression were squared you would say “... all squared.” Like this:

$$[(x + 2)(x + 1)]^2 = \text{“the quantity } x \text{ plus two, times the quantity } x \text{ plus one, all squared”}$$

Rule 4 — Fractions

Fractions are read as “*numerator over denominator.*” If either part is a group, it gets “the quantity.”

$$\frac{x}{x + 1} = \text{“} x \text{ over the quantity } x \text{ plus one”}$$

$$\frac{2x + 1}{x^2 - 1} = \text{“the quantity two } x \text{ plus one, over the quantity } x \text{ squared minus one”}$$

Putting It Together

Let’s read $(x + 2)(x + 1)^2 + 12$ step by step:

Piece	→	What you say
$(x + 2)$	→	“the quantity x plus two”
$\times$	→	“times”
$(x + 1)^2$	→	“the quantity x plus one, squared”
$+ 12$	→	“plus twelve”

Full reading: “*The quantity x plus two, times the quantity x plus one, squared, plus twelve.*”

One more: $\frac{x(x + 3)}{x^2 + 1}$ is read as “ *x times the quantity x plus three, over the quantity x squared plus one.*”

Now You Try

Write a complete English sentence for each expression.

1. $(x + 1)^2$

2. $\frac{x}{x + 1}$

3. $(2x + 1)(x - 3)$

4. $\frac{x + 2x}{x^2}$

5. $\frac{x^2 + 1}{(x - 1)^2}$

6. Reverse.

(a) “The quantity $2x$ minus one, squared.”

(b) “The quantity x plus three, over the quantity x minus three.”

(c) “Negative the quantity x squared plus one.”

(c) “Negative x squared plus one.”

(d) “The quantity x plus one, times the quantity x minus one, all squared, over x .”

(e) “The quantity x plus h , squared, minus x squared, all over h .”

Diagnostic Problems

Factor the following expressions. You may want to use a piece of scratch paper.

(a) $x^2 - 16$

(b) $2x^2 + 5x - 3$

(c) $x^4 - 81$

(d) $(x^2 + 3x)^2 - 2(x^2 + 3x) - 8$

(e) $x^4 + x^2 + 1$

(f) $x^4 + 4$

Part 3 — The Language of Math

Read carefully. These words appear in every math class from here on.

Math uses ordinary English words in precise ways. When a problem says *evaluate*, it means something different from *simplify*. When you *define* a variable, you are making a promise about what that symbol means for the rest of your work. Here are the words you will see most often:

Let — introduces a variable. “Let x be the width of the room” means: for everything that follows, x stands for that width. You are naming an unknown.

Define — give an exact, unambiguous meaning to a symbol or term. Defining $x = 5$ means x cannot also be 7. A definition is a commitment. If a problem asks you to *define a variable*, respond with a **let** statement: “Let x be the width of the room.”

Given — a fact that has been established or handed to you as true. You did not choose it; the problem did. “*Given $x = 4$, find $2x$.*” means: this equation is true — now work from it.

Suppose/Assume — temporarily accept something as true in order to explore what follows. “Suppose the width is 10” does not mean it is 10 — it means *what would happen if it were?*

Suppose/Assume ... Then — temporarily accept something as true in order to explore what follows. *Then* delivers the consequence. “Suppose the width is 10 blocks — then the total area is $5(10 + 3) = 65$.” The *suppose* sets up the condition; the *then* is what you conclude from it. This is the skeleton of almost every mathematical argument you will ever write.

Sentence	What it signals
<i>Given that it is raining, bring an umbrella.</i>	It is actually raining. This is a known fact. Act on it.
<i>Suppose it rains tomorrow, then bring an umbrella.</i>	We do not know if it will rain. We are planning for the possibility.
<i>Assume the store is open, then we can buy wool tonight.</i>	We are temporarily treating this as true to figure out what to do next. It might be wrong.

Evaluate — substitute a value and compute a number. “Evaluate $3x + 1$ when $x = 4$ ” means replace x with 4 and get 13. The answer is always an expression.

Simplify — rewrite an expression in a cleaner equivalent form. The answer is still an expression, not necessarily a number. $3x + 2x$ simplifies to $5x$; you have not changed the value, only the form.

Determine — find with certainty, and show why. Stronger than “guess” or “find” — it implies your answer must be justified. An example questions could be, “Determine the value of x such that $2x + 3 = 11$.”

Such that — a condition or constraint. “Find x such that $2x = 8$ ” means find the x that makes that statement true. Notice we could’ve also asked “Determine x such that $2x = 8$.”

Hence / Therefore / Thus — what comes next follows logically from what just came before. These are not filler words. Writing “therefore” is a claim that the next line is forced by the previous one. An example would be “ $2x = 8$, therefore $x = 4$.”

Conjecture — an educated guess you believe is true but have not yet proven. Mathematicians make conjectures all the time. Some stay unproven for centuries. You could be the next person to prove an important conjecture :)

Quick check — answer in one sentence each:

1. What is the difference between *evaluate* and *simplify*?

2. A classmate writes “let $x = 5$ ” at the top of their work, then uses $x = 7$ two lines later. What rule did they break?

3. Write a sentence using the word *such that* about anything — it does not have to be about math.

4. Rewrite this using the word *therefore*: “It is raining. I should bring an umbrella.”

5. Write a *suppose ... then* sentence about anything.

6. Write a conjecture about even numbers. You do not need to prove it.

7. Your friend says: “I assumed the store was open, so I walked over but found out it was actually closed.” Did your friend use *assumed* correctly? Explain.

8. Your friend says: “I defined n as an even number, but then I realized it was odd, so I changed it in the middle of the problem.” What rule did they break?

Part 4 — Real Life Application

You and a friend are building two bedrooms in Minecraft and need to figure out how much wool to collect to carpet both rooms. Each floor block needs exactly one carpet block, and each carpet block takes two wool to craft.

Both rooms are 10 blocks long and share a wall. Bedroom 2 will be 8 blocks wide. You haven't decided how wide Bedroom 1 will be yet.

1. How many carpet blocks do you need for Bedroom 2? _____
2. How much wool do you need for Bedroom 2? _____
3. How many carpet blocks do you need for Bedroom 1? _____
4. How much wool do you need for Bedroom 1? _____
5. How much wool do you need in total for both rooms? _____

★ *Make sure to take notes in a different color pen of where your brain might be setting warning lights off!*
